

Water sensitive urban design

Pervious paving

Summary

Pervious paving can be used as an alternative to traditional impervious hard surfaces used in roads, carparks, footpaths and public squares or plazas. Pervious pavement reduces runoff as some of the rainfall infiltrates into the soil below. Pervious pavement can also provide an additional water storage system. There is a variety of pervious pavements such as porous asphalt, porous turf, porous concrete and permeable paving blocks.

This brochure is part of a series that explain various aspects of water sensitive urban design. Please see *Water sensitive urban design in Western Australia* for background information on water sensitive urban design.

Main benefits

- They reduce the amount of directly connected impervious areas.
- Pervious paving reduces runoff rates and volumes.
- It allows runoff to soak into the ground in the same area it would have prior to urban development, rather than being conveyed away.
- It prevents pollutants being transported into other areas.

Design factors

- It requires a slope not steeper than 5%.
- Subsoil drainage may be required in low permeability soils.
- It is not suitable in sites with rising watertables, saline conditions or dispersive clays.

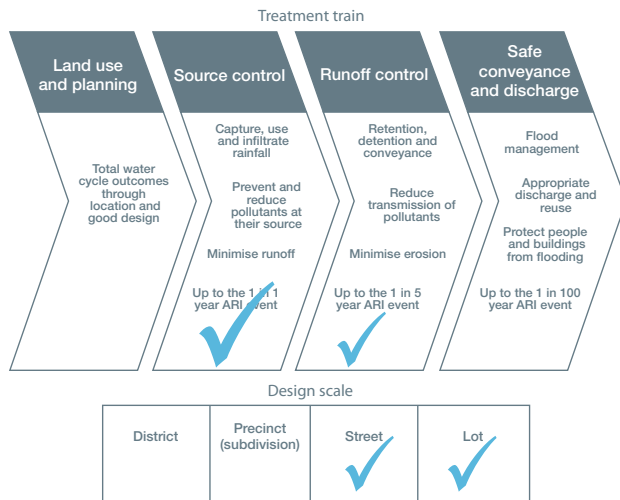

Target pollutants

- coarse sediment
- suspended solids
- heavy metals
- hydrocarbons such as oil and grease
